

# Outbreaks were observed only in the supercritical cases

Intervals are NOMINAL fixed-sample Wilson 95% intervals. Replicate counts are adaptive (pilot of 50 extended from  $\hat{p}$ , cap 1200, pilot pooled), so coverage under the realized design is UNASSESSED (owner ruling S2B-A7). Counts are printed per cell. The  $N = 10^6$  cells at  $\lambda = 2$  (open stars) are OUTSIDE the adaptive rule: a fixed 50-run design, not piloted and not extended, with no precision target.
